# **Key Architectural Decisions**

# **Modular Design**

Each system is self-contained with clear interfaces. The simulation can run independently of rendering, allowing for headless testing and different visualization modes.

#### **Worker-Based Simulation**

Heavy simulation work runs in web workers to maintain 60fps rendering while complex ecosystem calculations happen in background threads.

#### **Asset Pipeline**

Separate tools process raw assets into optimized engine formats. This allows for artist-friendly input formats while maintaining performance.

### **Data-Driven Configuration**

Species behaviors, environmental parameters, and dungeon generation rules are externalized to JSON files for easy modification without code changes.

#### **Scalable Rendering**

The rendering system supports both high-detail individual creature rendering and efficient instanced rendering for population visualization.

## **Debug-First Development**

Extensive debugging and visualization tools are built into the architecture from the start, making development and ecosystem tuning much easier.

This structure supports both the complex ecological simulation and the 3D visualization requirements while maintaining clean separation of concerns and scalability for future features.
